

Authentication API Testing

Test Summary Report – SQA Internship Day 6

1. Objective

To test authentication-related API behavior including registration, login, input validation, security-oriented inputs, token availability, and authorization considerations using Postman.

2. API and Tool

API: ReqRes Demo API. Tool: Postman. Primary endpoints used: POST /api/register and POST /api/login.

3. Test Coverage

Registration, valid login, invalid login, missing required fields, email validation, password validation, security input handling, logout consideration, unauthorized-access consideration, and response validation.

4. Test Cases

32 planned test cases are included in the accompanying test-case document. Executed results should be updated from the actual Postman runs.

5. Current Observed Result

TC-006 valid login returned 200 OK with a token. TC-007 invalid-password test unexpectedly returned 200 OK with a token, so TC-007 is recorded as a failed test/confirmed observation requiring verification.

6. Blocked / N/A

Logout and protected-resource authorization tests are blocked/N/A for the current /api/login demo flow because the required logout/protected-resource behavior is not part of that flow.

7. Automated Validation

Postman tests should validate HTTP status, response time, token availability, and required JSON fields. The exact pass/fail counts must be taken from the Postman Test Results after execution.

8. Conclusion

The collection provides a practical authentication-testing suite. Before final submission, execute all pending cases, update actual results and statuses, export the collection, and attach screenshots and the final report.
